## The Mole <br> Unit Conversions

It's all about laying out your problem in a stepwise, logical manner, so you can solve it. LEARN HOW!

## Conversions in the every day

There are terms we use every day like "dozen," which you all know means 12 , to describe how much of something you have. You can convert between different units as long as they measure the same thing (like feet, and meters both measure distance)

Ex. Timmy has 18 eggs, how many dozen eggs does he have?
This is how to set up a unit conversion problem properly!!!

$$
18 \text { eggs } \times \frac{1 \text { dozen }}{12 \text { eggs }}=1.5 \text { dozen }
$$

## Metric System conversions

The metric system is based around 10's (like scientific notation) with prefixes denoting the power on the 10 . Common prefixes are centi $\left(10^{-2}\right)$, milli $\left(10^{-3}\right)$, kilo( $10^{3}$ ), micro( $10^{-6}$ ), mega( $10^{6}$ ), nano( $10^{-9}$ ), giga( $10^{9}$ ),

Ex. Convert 1.8 km into meters

Ex. Convert 1.8 km into centimeters

Ex. Convert 5.4 Gm into nm

Or...

## Formula Masses

Chemical formulas represent the number and type of each atom present in a compound or element (recall law of definite proportions)

Ex. $\quad \mathrm{NaCl}: \quad 1$ sodium atom and 1 chlorine atom
$\mathrm{H}_{2} \mathrm{SO}_{4}$ : 2 hydrogen atoms, 1 sulphur atom, and 4 oxygen atoms
The law of conservation of mass states that mass is neither created nor destroyed in a chemical reaction. Therefore the mass of a formula unit can be determined by adding together the masses of each atom present.

The term "formula mass" applies to atoms, molecules and ionic compounds; "molecular mass" only applies to covalent compounds

## Relative Atomic Masses

Relative mass: comparing the mass of one object to the mass of another
Ex. A certain number of oranges have a mass of 3000 g and an equal number of grapefruits have a mass of 5000 g . What fraction of the mass of the grapefruits do the oranges have?

$$
\frac{3000 \mathrm{~g}}{5000 \mathrm{~g}}=0.6 \Leftarrow \text { ratio of orange to grapefruit mass (relative mass) }
$$

(Note that the mass of an individual orange or grapefruit is not known)
In the same way, scientists have determined the relative masses of atoms. The units used to measure mass of atoms is the atomic mass unit or amu which has the SI unit symbol $\mathbf{u}$.

The carbon- 12 atom is assigned a mass of $\mathbf{1 2 u}$ so one $\mathbf{u}$ is equal to $\frac{1}{12}$ the mass of a single caron-12 atom

## Calculating Formula Masses (a strategy)

1) Determine the number of atoms of each element present:

Ex. $\mathrm{Fe}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{3}$
1 Fe
6 C
9 H
60
2) Look up the atomic masses on the periodic table (keep at least one decimal place):

$$
\begin{array}{llll}
\mathrm{Fe}=55.8 \mathrm{u} & \mathrm{C}=12.0 \mathrm{u} & \mathrm{H}=1.01 \mathrm{u} & \mathrm{O}=16.0 \mathrm{u}
\end{array}
$$

3) Multiply the masses by the number of each atom present

$$
\begin{aligned}
& \mathrm{Fe}=1(55.8)=55.8 \mathrm{u} \\
& \mathrm{C}=6(12.0)=72.0 \mathrm{u} \\
& \mathrm{H}=9(1.01)=9.09 \mathrm{u} \\
& \mathrm{O}=6(16.0)=96.0 \mathrm{u}
\end{aligned}
$$

4) Add the masses together:

$$
55.8 u+72.0 u+9.09 u+96.0 u=232.9 u
$$

Thus the formula mass of $\mathrm{Fe}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{3}$ is 232.9 u
Try these: $\mathrm{NaCl}, \mathrm{CO}_{2}, \mathrm{CaC}_{2} \mathrm{O}_{4}$
$\mathrm{NaCl}=$
$\mathrm{CO}_{2}=$
$\mathrm{CaC}_{2} \mathrm{O}_{4}=$

## Avogadro's Number and the Mole

The mole or 'moles' is just a way of measuring the amount of things, just like a dozen. Except where a dozen means 12 things, a mole means: $602,000,000,000,000,000,000,000$ (yes, $6.02 \times 10^{23}$ ) things!!!

An amu is far too small to measure in the lab, so chemicals are measured in grams. To be of use we need to know how many ${ }_{6}^{12} \mathrm{C}$ atoms have a mass of exactly 12 grams. This number was found to be about $6.02214 \times 10^{23}$ atoms.

We call this number Avogadro's number ( $\mathrm{N}_{\mathrm{A}}$ ) named after an Italian scientist.

So just like we can do a calculation to figure out how many dozen are 54 eggs. We can do calculations to figure out how many moles of an atom we have if we have... say $5.0 \times 10^{22}$ atoms.

$$
5.0 \times 10^{22} \text { atoms } \times \frac{1 \mathrm{~mole}}{6.022 \times 10^{23} \text { atoms }}=0.083 \mathrm{moles}
$$

If you look at the periodic table carbon has an atomic mass of 12.011 u not 12 exactly. This is due to the presence of isotopes (recall from science 10)

Isotopes are atoms of the same element (same \# protons) but with a difference in \# neutrons.

Most elements occur naturally as mixtures of different isotopes.
Ex. Carbon contains $98.89 \%{ }_{6}^{12} \mathrm{C}$ and $1.11 \%{ }_{6}^{13} \mathrm{C}$ (contains an extra neutron)
Atomic mass is a weighted average based on abundance of each isotope.

## Moles $\leftrightarrow$ Molecules

To convert from the number of moles of particles to the number of particles:

$$
\text { number of moles } \times \frac{6.022 \times 10^{23} \text { atoms }}{1 \text { mole }}=\text { number of particles }
$$

Ex. How many sodium atoms are in 2.50 moles of sodium?

To convert from the number of particles to the number of moles of particles:

Ex. How many moles of hydrogen molecules are there in $3.01 \times 10^{24}$ molecules of $\mathrm{H}_{2}$ ?

## Molar Mass

One mole of particles has a mass in grams equal to the mass of one particle in amu

Ex. Carbon-12 $=12 \mathrm{u}$, so one mole would be 12 g
Oxygen $=32 \mathrm{u}$, so one mole would be 32 g
$\mathrm{NaCl}=58.5 \mathrm{u}$, so one mole is 58.5 g etc...
The molar mass in grams has the same numerical value as the formula mass in amu, but now we're dealing with values we can measure in the lab

Molar mass can also be used as a unit conversion (show as a ratio)
If NaCl has a mass of 58.5 g per mole we can write it as: $\frac{58.5 \mathrm{~g}}{1 \mathrm{~mole}}$ or $\frac{1 \mathrm{~mole}}{58.5 \mathrm{~g}}$
Ex. How many grams would 0.250 mol of water weigh?

1) calculate the molar mass of $\mathrm{H}_{2} \mathrm{O}: 2(1.0)+16.0=18.0 \mathrm{~g} \cdot \mathrm{~mol}^{-1}$
2) multiply by number of moles:

$$
0.250 \text { moles of } \mathrm{H}_{2} \mathrm{O} \times \frac{18.0 \mathrm{~g}}{1 \text { mole }}=4.50 \mathrm{~g} \mathrm{of}_{2} \mathrm{O}
$$

## Percent Composition and Empirical Formulae

Percent composition gives you the percentage amount of an element (or both elements) in a compound

Ex. Percent composition of a sample of containing 4.00 g of hydrogen and 32.0 g of oxygen

Ex. Percent composition of sulphuric acid ( $\mathrm{H}_{2} \mathrm{SO}_{4}$ ) (Try this one!)

Empirical formula gives you the lowest possible ratio of elements in a compound. For example $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ (glucose) would have an empirical formula of $\mathrm{CH}_{2} \mathrm{O}$, even though it's 6 times that in reality.

Ex. Some compound has 50.4 g of nitrogen, and 115.8 g of oxygen (from elemental analysis):

Ratio of moles of N : moles of O (put the smaller \# moles on the bottom)

So the empirical formula is $\qquad$ (which has a molar mass of $\qquad$ )

Molecular formula has to be a multiple of the empirical formula:
Where $\mathrm{n}=$ molar mass of compound (has to be given - from mass spec) molar mass of empirical formula
$\mathrm{n}=$

Ex. Empirical formula of a compound with $58.5 \% \mathrm{C}, 7.4 \% \mathrm{H}$ and $34.1 \% \mathrm{~N}$
TRICK: Imagine you have 100.0 g of this compound, then there would be $58.5 \mathrm{~g} \mathrm{C}, 7.4 \mathrm{~g} \mathrm{H}$ and 34.1 g N

## Ex. Empirical formula of Rust

| Mass of rust analyzed | 15.53 g |
| :--- | ---: |
| Mass of iron in sample | -10.87 g |
| Mass of oxygen | $=4.66 \mathrm{~g}$ |

## Avogadro's Hypothesis and STP

STP: Standard Temperature and Pressue

- Gas volumes vary with temperature (PV = nRT)
- Standard conditions chosen so gases can be compared
- Standard T $=0^{\circ} \mathrm{C}$ (or 273 K )
- Standard $\mathrm{P}=1 \mathrm{~atm}$ (101.3 kPa)

## History of gas and the mole

Early 19 ${ }^{\text {th }}$ century: Chemists reacted gases together and compared ratios of gas volumes and masses
Dalton: Atoms react in fixed simple whole number ratios
Gay-Lussac: Law of combining volumes: gases combine in volumes of fixed whole number ratios
Avogadro: saw that the atom and gas-volume ratios were identical; and that some gases consisted of atoms and some were molecules

Avogadro's hypothesis (1811): equal volumes of different gases at the same T and P contain the same number of particles!

1 mole of a gas (any gas, but ONLY gases!) has a volume of 22.4 L at STP
Thus the molar mass of any unknown substance (converted to a gas) can be determined

Recall that several elements exist as diatomic molecules: $\mathrm{H} \mathrm{O}, \mathrm{N}, \mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}$ so that 22.4 L of oxygen at STP has $6.02 \times 10^{23}$ molecules, but $1.20 \times 10^{24}$ atoms of O

Ex. A 34.0 g sample of an unknown gas has a volume of 12.0 L at STP. What is its molecular mass?

Ex. What is the mass of 3.5 L of $\mathrm{NO}_{2}$ gas (at STP)?

Ex. What mass does a molar volume of $\mathrm{CO}_{2}$ gas have at $100^{\circ} \mathrm{C}$ ?
The mass of 1 molar volume of any gas is it's molar mass, so for $\mathrm{CO}_{2}$ it's just: $12.0+2(16.0)=44.0 \mathrm{~g} / \mathrm{mol}=\mathbf{4 4 . 0 g}$

## Moles and Solutions

## Molarity

The number of moles in a given volume of solution describes the concentration of that solution.

The molar concentration we call the Molarity (M) of a solution. It is measured by the number of dissolved moles of solute per liter of solution.

$$
\begin{array}{ll}
\mathrm{M}=\frac{\mathrm{n}}{\mathrm{~V}} \quad \text { Where, } \quad & \mathrm{n}=\text { \# of moles } \\
& \mathrm{V}=\text { volume of solution } \\
& M=\text { molarity (concentration) }
\end{array}
$$

The shorthand symbol for "molar concentration of $X$ " is a set of square brackets: [X]

Ex. What is the molarity of a solution made by dissolving 3.0 mol of salt $(\mathrm{NaCl})$ in 1.5 L of water

## Technique for preparing a solution

1) Calculate the mass of solid required
2) Weigh out on a balance
3) Transfer the solid quantitatively (all of it!) to a volumetric flask
4) Add water to dissolve, swirl until mostly dissolved
5) add water up to mark and mix by inversion

Ex. Describe how you would prepare 1.00 L of a 0.100 M solution of NaCl

Weigh out 5.85 g of NaCl on a balance, quantitatively transfer the solid to a volumetric flask and dissolve with sufficient water, add enough water to make up to the line on the volumetric flask. Done!

Mole Wheel
